Group A

Assignment No: 7

Title of the Assignment: Text Analytics

- 1. Extract Sample document and apply following document pre-processing methods: Tokenization, POS Tagging, stop words removal, Stemming and Lemmatization.
- 2. Create representation of document by calculating Term Frequency and Inverse Document Frequency.

Objectives of assignments: Student should be able to implement text analytics operations using python.

Prerequisite:

- 1. Basic of python programming
- 2. Concept of python NLKT (Natural language toolkit)
- 3. Apply pre-processing methods such as Tokenization, POS Tagging, stop words removal, Stemming and Lemmatization

Content for theory:

- 1. Text Analytics and NLP
- 2. Text Analysis Operations using NLTK
- 3. Tokenization
- 4. Sentence Tokenization
- 5. Word Tokenization
- 6. Frequency Distribution
- 7. POS Tagging
- 8. Stop words
- 9. Removing Stop words
- 10. Stemming:
- 11. Lemmatization:
- 12. Term Frequency (TF)
- 13. Inverse Document Frequency (IDF)
- 14. Implementing TF-IDF in Python from Scratch

1.Text Analytics and NLP:

Text Analytics has lots of applications in today's online world. By analysing tweets on Twitter, we can find trending news and peoples reaction on a particular event. Amazon can understand user feedback or review on the specific product. Book My Show can discover people's opinion about the movie. YouTube can also analyse and understand people's viewpoints on a video. Text communication is one of the most popular forms of day-to-day conversion. We chat, message, tweet, share status, email, write blogs, share opinion and feedback in our daily routine. All of these activities are generating text in a significant amount, which is unstructured in nature. In this area of the online marketplace and social media, it is essential to analyse vast of understand opinion. quantities data. to people's NLP enables the computer to interact with humans in a natural manner. It helps the computer to understand the human language and derive meaning from it. NLP is applicable in several problematic from speech recognition, language translation, classifying documents to information extraction. Analysing movie review is one of the classic examples to demonstrate a simple NLP Bag-of-words model, on movie reviews.

2.Text Analysis Operations using NLTK:

NLTK is a powerful Python package that provides a set of diverse natural languages algorithms. It is free, opensource, easy to use, large community, and well documented. NLTK consists of the most common algorithms such as tokenizing, part-of-speech tagging, stemming, sentiment analysis, topic segmentation, and named entity recognition. NLTK helps the computer to analysis, pre-process, and understand the written text.

```
!pip install nltk

Requirement already satisfied: nltk
in/home/northout/anaconda2/lib/python2.7/site-packages

Requirement already satisfied: six in
/home/northout/anaconda2/lib/python2.7/site-packages (from nltk)

[33mYou are using pip version 9.0.1, however version 10.0.1 is available.

You should consider upgrading via the 'pip install --upgrade pip' command.[0m
```

```
#Loading NLTK
import nltk
nltk.download('punkt')
```

3. Tokenization:

Tokenization is the first step in text analytics. The process of breaking down a text paragraph into smaller chunks such as words or sentence is called Tokenization. Token is a single entity that is building blocks for sentence or paragraph.

4. Sentence Tokenization:

Sentence tokenizer breaks text paragraph into sentences.

```
from nltk.tokenize import sent_tokenize

text="""Hello Mr. Smith, how are you doing today? The weather is
great, and city is awesome. The sky is pinkish-blue. You shouldn't
eat cardboard"""

tokenized_text=sent_tokenize(text)

print(tokenized_text)
```

```
>>['Hello Mr. Smith, how are you doing today?', 'The weather is great, and city is awesome.', 'The sky is pinkish-blue.', "You shouldn't eat cardboard"]
```

Here, the given text is tokenized into sentences.

5.Word Tokenization:

Word tokenizer breaks text paragraph into words.

```
from nltk.tokenize import word_tokenize
tokenized_word=word_tokenize(text)
print(tokenized_word)
```

```
>>['Hello', 'Mr.', 'Smith', ',', 'how', 'are', 'you', 'doing', 'today', '?', 'The', 'weather', 'is', 'great', ',', 'and', 'city', 'is', 'awesome', '.', 'The', 'sky', 'is', 'pinkish-blue', '.', 'You', 'should', "n't", 'eat', 'cardboard']
```

6.Frequency Distribution:

```
from nltk.probability import FreqDist
fdist = FreqDist(tokenized_word)
print(fdist)
```

<FreqDist with 25 samples and 30 outcomes>

fdist.most common(2)

>>[('is', 3), (',', 2)]

#Frequency Distribution Plot

#pip install matplotlib
import matplotlib.pyplot as plt

fdist.plot(30,cumulative=False)

plt.show()

6.POS Tagging:

The primary target of Part-of-Speech (POS) tagging is to identify the grammatical group of a given word. Whether it is a NOUN, PRONOUN, ADJECTIVE, VERB, ADVERBS, etc. based on the context. POS Tagging looks for relationships within the sentence and assigns a corresponding tag to the word.

```
sent = "Albert Einstein was born in Ulm, Germany in 1879."
```

```
tokens=nltk.word_tokenize(sent)
print(tokens)
```

```
>>['Albert', 'Einstein', 'was', 'born', 'in', 'Ulm', ',', 'Germany', 'in', '1879', '.']
```

```
nltk.download('averaged_perceptron_tagger')
nltk.pos_tag(tokens)
```

```
[('Albert', 'NNP'),
  ('Einstein', 'NNP'),
  ('was', 'VBD'),
  ('born', 'VBN'),
  ('in', 'IN'),
  ('ulm', 'NNP'),
  (',', ','),
  ('Germany', 'NNP'),
  ('in', 'IN'),
  ('1879', 'CD'),
  ('.', '.')]
```

7.Stopwords:

Stop words considered as noise in the text. Text may contain stop words such as is, am, are, this, a, an, the, etc. In NLTK for removing stop words, you need to create a list of stop words and filter out your list of tokens from these words.

```
from nltk.corpus import stopwords
stop_words=set(stopwords.words("english"))
print(stop_words)
```

>>{'their', 'then', 'not', 'ma', 'here', 'other', 'won', 'up', 'weren', 'being', 'we', 'those', 'an', 'them', 'which', 'him', 'so', 'yourselves', 'what', 'own', 'has', 'should', 'above', 'in', 'myself', 'against', 'that', 'before', 't', 'just', 'into', 'about', 'most', 'd', 'where', 'our', 'or', 'such', 'ours', 'of', 'doesn', 'further', 'needn', 'now', 'some', 'too', 'hasn', 'more', 'the', 'yours', 'her', 'below', 'same', 'how', 'very', 'is', 'did', 'you', 'his', 'when', 'few', 'does', 'down', 'yourself', 'i', 'do', 'both', 'shan', 'have', 'itself', 'shouldn', 'through', 'themselves', 'o', 'didn', 've', 'm', 'off', 'out', 'but', 'and', 'doing', 'any', 'nor', 'over', 'had', 'because', 'himself', 'theirs', 'me', 'by', 'she', 'whom', 'hers', 're', 'hadn', 'who', 'he', 'my', 'if', 'will', 'are', 'why', 'from', 'am', 'with', 'been', 'its', 'ourselves', 'ain', 'couldn', 'a', 'aren', 'under', 'll', 'on', 'y', 'can', 'they', 'than', 'after', 'wouldn', 'each', 'once', 'mightn', 'for', 'this', 'these', 's', 'only', 'haven', 'having', 'all', 'don', 'it', 'there', 'until', 'again', 'to', 'while', 'be', 'no', 'during', 'herself', 'as', 'mustn', 'between', 'was', 'at', 'your', 'were', 'isn', 'wasn'}

8.Removing Stop words:

```
filtered_sent=[]
for w in tokenized_sent:
    if w not in stop_words:
        filtered_sent.append(w)

print("Tokenized Sentence:", tokenized_sent)
print("Filterd Sentence:", filtered sent)
```

```
>>Tokenized Sentence: ['Hello', 'Mr.', 'Smith', ',', 'how', 'are',
'you', 'doing', 'today', '?']

Filterd Sentence: ['Hello', 'Mr.', 'Smith', ',', 'today', '?']
```

9.Stemming:

Stemming is a process of linguistic normalization, which reduces words to their word root word or chops off the derivational affixes. For example, connection, connected, connecting word reduce to a common word "connect".

```
# Stemming
from nltk.stem import PorterStemmer
from nltk.tokenize import sent_tokenize, word_tokenize

ps = PorterStemmer()

stemmed_words=[]
for w in filtered_sent:
    stemmed_words.append(ps.stem(w))

print("Filtered Sentence:", filtered_sent)
print("Stemmed Sentence:", stemmed_words)
```

```
>>Filtered Sentence: ['Hello', 'Mr.', 'Smith', ',', 'today', '?']

Stemmed Sentence: ['hello', 'mr.', 'smith', ',', 'today', '?']
```

10.Lemmatization:

Lemmatization reduces words to their base word, which is linguistically correct lemmas. It transforms root word with the use of vocabulary and morphological analysis. Lemmatization is usually more sophisticated than stemming. Stemmer works on an individual word without knowledge of the context. For example, the word "better" has "good" as its lemma. This thing will miss by stemming because it requires a dictionary look-up.

```
#Lexicon Normalization
#performing stemming and Lemmatization

from nltk.stem.wordnet import WordNetLemmatizer
lem = WordNetLemmatizer()

from nltk.stem.porter import PorterStemmer
stem = PorterStemmer()

word = "flying"
print("Lemmatized Word:",lem.lemmatize(word,"v"))
print("Stemmed Word:",stem.stem(word))
```

```
Lemmatized Word: fly
Stemmed Word: fli
```

11.Term Frequency (TF):

Suppose we have a set of English text documents and wish to rank which document is most relevant to the query, "Data Science is awesome!" A simple way to start out is by eliminating documents that do not contain all three words "Data", "is", "Science", and "awesome", but this still leaves many documents. To further distinguish them, we might count the number of times each term occurs in each document; the number of times a term occurs in a document is called its *term frequency*.

The weight of a term that occurs in a document is simply proportional to the term frequency. Formula:

 $tf(t,d) = count \ of \ t \ in \ d \ / \ number \ of \ words \ in \ d$

Document Frequency:

This measures the importance of document in whole set of corpus, this is very similar to TF. The only difference is that TF is frequency counter for a term t in document d, whereas DF is the count of **occurrences** of term t in the document set N. In other words, DF is the number of documents in which the word is present. We consider one occurrence if the term consists in the document at least once, we do not need to know the number of times the term is present.

 $df(t) = occurrence \ of \ t \ in \ documents$

12.Inverse Document Frequency (IDF):

While computing TF, all terms are considered equally important. However, it is known that certain terms, such as "is", "of", and "that", may appear a lot of times but have little importance. Thus, we need to weigh down the frequent terms while scale up the rare ones, by computing IDF, an *inverse document frequency* factor is incorporated which diminishes the weight of terms that occur very frequently in the document set and increases the weight of terms that occur rarely.

IDF is the inverse of the document frequency which measures the informativeness of term t. When we calculate IDF, it will be very low for the most occurring words such as stop words (because stop words such as "is" is present in almost all of the documents, and N/df will give a very low value to that word). This finally gives what we want, a relative weightage.

$$idf(t) = N/df$$

Now there are few other problems with the IDF, in case of a large corpus, say 100,000,000, the IDF value explodes, to avoid the effect we take the log of idf. During the query time, when a word which is not in vocab occurs, the df will be 0. As we cannot divide by 0, we smoothen the value by adding 1 to the denominator. that's the final formula:

Formula:

$$idf(t) = log (N/(df + 1))$$

tf-idf now is a the right measure to evaluate how important a word is to a document in a collection or corpus. here are many different variations of TF-IDF but for now let us concentrate on the this basic version.

Formula:

$$tf$$
- $idf(t, d) = tf(t, d) * log(N/(df + 1))$

13.Implementing TF-IDF in Python From Scratch:

To make TF-IDF from scratch in python,let's imagine those two sentences from diffrent document: first_sentence: "Data Science is the sexiest job of the 21st century". second_sentence: "machine learning is the key for data science".

First step we have to create the TF function to calculate total word frequency for all documents. Here are the codes below:

first as usual we should import the necessary libraries:

```
import pandas as pd
import sklearn as sk
import math
```

so let's load our sentences and combine them together in a single set:

```
first_sentence = "Data Science is the sexiest job of the 21st
century"
second_sentence = "machine learning is the key for data
science"#split so each word have their own stringfirst_sentence
= first_sentence.split(" ")
second_sentence = second_sentence.split(" ")#join them to remove
common duplicate words
total=
set(first_sentence).union(set(second_sentence))print(total)
```

Output:

```
{'data', 'Science', 'job', 'sexiest', 'the', 'for', 'science',
'machine', 'of', 'is', 'learning', '21st', 'key', 'Data',
'century'}
```

Now let's add a way to count the words using a dictionary key-value pairing for both sentences:

```
wordDictA = dict.fromkeys(total, 0)
wordDictB = dict.fromkeys(total, 0)for word in first_sentence:
    wordDictA[word]+=1

for word in second_sentence:
    wordDictB[word]+=1
```

Now we put them in a dataframe and then view the result:

```
pd.DataFrame([wordDictA, wordDictB])
```

```
[7]: 21st Data Science century data for is job key learning machine of science sexiest the

1 0 0 0 0 0 1 1 1 0 0 1 1 0 0 1 1 0 0 1
```

No let's writing the TF Function:

```
def computeTF(wordDict, doc):
    tfDict = {}
    corpusCount = len(doc)
    for word, count in wordDict.items():
        tfDict[word] = count/float(corpusCount)
    return(tfDict) # running our sentences through the tf
function:tfFirst = computeTF(wordDictA, first_sentence)
tfSecond = computeTF(wordDictB, second_sentence) # Converting to
dataframe for visualizationtf = pd.DataFrame([tfFirst,
tfSecond])
```

and this is the expected output:

	21st	Data	Science	century	data	for	is	job	key	learning	machine	of	science	sexiest	the
0	0.1	0.1	0.1	0.1	0.000	0.000	0.100	0.1	0.000	0.000	0.000	0.1	0.000	0.1	0.200
1	0.0	0.0	0.0	0.0	0.125	0.125	0.125	0.0	0.125	0.125	0.125	0.0	0.125	0.0	0.125

That's all for TF formula, just i wanna talk about stop words that we should eliminate them because they are the most commonly occurring words which don't give any additional value to the document vector .in-fact removing these will increase computation and space efficiency. nltk library has a method to download the stopwords, so instead of explicitly mentioning all the stopwords ourselves we can just use the nltk library and iterate over all the words and remove the stop words. There are many efficient ways to do this, but ill just give a simple method.

those a sample of a stopwords in english language:

```
> stopwords("english")
 [1] "i"
                                "my"
                   "me"
                                             "mvself"
                                                           "we"
  [6] "our"
                                "ourselves" "you"
                   "ours"
                                                           "your"
                                "yourselves" "he"
 [11] "yours"
                   "yourself"
                                                           "him"
                   "himself"
                                "she"
                                             "her"
                                "its"
 [21] "herself"
                   "it"
                                             "itself"
                                                           "they"
 [26] "them"
                   "their"
                                "theirs"
                                              "themselves" "what"
 [31] "which"
                   "who"
                                "whom"
                                              "this"
                                                           "that"
 [36] "these"
                   "those"
                                "am"
                                              "is"
                                                           "are"
                                              "been"
 [41] "was"
                   "were"
                                "be"
                                                           "being"
 [46] "have"
                   "has"
                                "had"
                                              "having"
                                                           "do"
```

and this is a simple code to download stop words and removing them.

```
import nltknltk.download('stopwords') from nltk.corpus import
stopwordsstop_words =
set(stopwords.words('english')) filtered_sentence = [w for w in
wordDictA if not w in stop_words]print(filtered_sentence)
```

Output:

```
['data', 'Science', 'job', 'sexiest', 'science', 'machine',
'learning', '21st', 'key', 'Data', 'century']
```

And now that we finished the TF section, we move onto the IDF part:

```
def computeIDF(docList):
    idfDict = {}
    N = len(docList)

idfDict = dict.fromkeys(docList[0].keys(), 0)
    for word, val in idfDict.items():
        idfDict[word] = math.log10(N / (float(val) + 1))

return(idfDict)#inputing our sentences in the log file
idfs = computeIDF([wordDictA, wordDictB])
```

and now we implement the idf formula, let's finish with calculating the TFIDF

```
def computeTFIDF(tfBow, idfs):
    tfidf = {}
    for word, val in tfBow.items():
        tfidf[word] = val*idfs[word]
    return(tfidf)
#running our two sentences through the IDF:idfFirst =
computeTFIDF(tfFirst, idfs)
idfSecond = computeTFIDF(tfSecond, idfs)
#putting it in a dataframe
idf= pd.DataFrame([idfFirst, idfSecond])
print(idf)
```

Output:

```

```

That was a lot of work. But it is handy to know, if you are asked to code TF-IDF from scratch in the future. However, this can be done a lot simpler thanks to sklearn library. Let's look at the example from them below:

```
#first step is to import the libraryfrom
sklearn.feature_extraction.text import TfidfVectorizer
#for the sentence, make sure all words are lowercase or you will
run #into error. for simplicity, I just made the same sentence
all #lowercasefirstV= "Data Science is the sexiest job of the
21st century"
secondV= "machine learning is the key for data science"#calling
the TfidfVectorizer
vectorize= TfidfVectorizer()
#fitting the model and passing our sentences right
away:response= vectorize.fit_transform([firstV, secondV])
```

Output:

```
19]: print(response)
       (0, 1)
                    0.34211869506421816
       (0, 0)
                     0.34211869506421816
       (0, 9)
                     0.34211869506421816
       (0, 5)

```

Conclusion:

In this tutorial, you have learned what Text Analytics is, NLP and text mining, basics of text analytics operations using NLTK such as Tokenization, Normalization, Stemming, Lemmatization and POS tagging. What are sentiment analysis and text classification using scikit-learn

Questions:

- 1. What is Tokenization?
- 2. What is POS Tagging?
- 3. What are stop words?
- **4.** What is Stemming and Lemmatization?
